Call a method in a Form from another class!

1- create public class and define public static variable like this:

```csharp
public class General
    {
        public General()
        {

        }

        public static frmMain mainForm;  //we use this as a handle to the main form(frmMain)
```

2- In the Form_load event assign value to your reference variable

```csharp
private void frmMain_Load(object sender, EventArgs e)
        {

            General.mainForm = this;        //set a reference back to this form

            //---do more stuff

        }
```

3- Finally, in your custom class you can call all public functions inside the form:

```csharp
public class Communication
    {

        internal static void ParseData(string XBEEData)
            {
                        //---break the stream and assign to the properties in General.
                        try
                        {
                            // parse com port data here…

                             //---update the GUI with a call to the form's method
                            General.mainForm.UpdateGUI();

                        }

            }
```
